## **Learning objectives**

- Define mixed effects models and population average models
- 2 Perform model diagnostics for random effects models
- 3 Interpret random intercepts and random slopes
- 4 Define and perform population average models
- 5 Define assumptions on correlation structure in hierarchical models
- 6 Choose between hierarchical modeling strategies

### Fecal fat dataset

- Lack of digestive enzymes in the intestine can cause bowel absorption problems.
  - This will be indicated by excess fat in the feces.
  - Pancreatic enzyme supplements can alleviate the problem.
  - fecfat.csv: a study of fecal fat quantity (g/day) for individuals given each of a placebo and 3 types of pills

**Table 7.1** Fecal fat (g/day) for six subjects

Subject number	Pill type				Subject
	None	Tablet	Capsule	Coated	Average
1	44.5	7.3	3.4	12.4	16.9
2	33.0	21.0	23.1	25.4	25.6
3	19.1	5.0	11.8	22.0	14.5
4	9.4	4.6	4.6	5.8	6.1
5	71.3	23.3	25.6	68.2	47.1
6	51.2	38.0	36.0	52.6	44.5
Pill type					
average	38.1	16.5	17.4	31.1	25.8

#### Nonhierarchical analysis strategies

Mixed effects models

Longitudinal data

Population Average Models

# Non-hierarchical analysis strategies for hierarchical data

- Analyses for each subgroup
  - e.g., look at each patient independently
  - doesn't work at all in this example, and in general is not an integrated analysis of the whole data
  - could sort of work for an example with many patients per doctor, a few doctors
- Analysis at the highest level in the hierarchy
  - first summarize data to highest level
  - doesn't work at all in this example
  - could sort of work for an example with few patients per doctor, many doctors
- Analysis on "Derived Variables"
  - consider each treatment type separately, take differences in fat levels between treatment/control for each patient and use paired t-tests
  - can work, but not for unbalanced groups
- Fixed-effects models

Levi Waldron

Learning objectives and outline

Review

Nonhierarchical analysis strategies

Mixed effects models

Longitudinal data

Population Average Models

# When is hierarchical analysis definitely needed?

- 1 the correlation structure is of interest, *e.g.* familial aggregation of disease, or consistency of treatment within centers
- 2 we wish to "borrow strength" across the levels of a hierarchy in order to improve estimates
- 3 dealing with unbalanced data
- 4 we want to benefit from software designed for hierarchical data

#### Levi Waldron

#### Review

Nonhierarchical analysis strategies

## Mixed effects models

Longitudinal data

Population Average Models

## Mixed effects models

Model looks like two-way ANOVA:

$$FECFAT_{ij} = \beta_0 + \beta_{subjecti}SUBJECT_i + \beta_{pilltypej}PILLTYPE_j + \epsilon_{ij}$$

• Assumption:  $\epsilon_i \stackrel{iid}{\sim} N(0, \sigma_{\epsilon}^2)$ 

ullet But instead of fitting a eta to each individual, we assume that the subject effects are selected from a distribution of possible subject effects:

$$FECFAT_{ij} = \beta_0 + SUBJECT_i + \beta_{pilltypej}PILLTYPE_j + \epsilon_{ij}$$

Where we assume:  $SUBJECT_i \stackrel{iid}{\sim} N(0, \tau_{00}^2)$ 

- This is a *mixed effects* model because:
  - the "true" intercept varies randomly from patient to patient
  - the "true" (population) coefficient of treatment is fixed (the same for everyone)

#### Mixed effects models

Longitudinal

Population Average Models

## Assumptions of the mixed model

$$\textit{FECFAT}_{ij} = \beta_0 + \textit{SUBJECT}_i + \beta_{\textit{pilltypej}} \textit{PILLTYPE}_j + \epsilon_{ij}$$

- Normally distributed residuals as in fixed effects model:
  - $\epsilon_i \stackrel{iid}{\sim} N(0, \sigma_{\epsilon}^2)$
- Normally distributed **latent variable**:
  - SUBJECT<sub>i</sub>  $\stackrel{iid}{\sim} N(0, \tau_{00}^2)$

## Longitudinal data examples

- Example 1: a measure of sleepiness before and after administration of treatment or placebo
- Example 2: Study of Osteoporotic Fractores (SOF dataset)
  - 9,704 women tracked with clinical visits every two years
  - Bone Mineral Density (BMD), Body Mass Index (BMI), many other variables
- Questions for Example 2:
  - 1 Is change in BMD related to age at menopause? This is a time-invariant predictor, age at menopause, with time-dependent changes in the outcome, BMD.
  - 2 Is change in BMD related to change in BMI? This is an analysis relating a time-varying predictor, BMI, with changes in the outcome, BMD. BMI varies quite a lot between women, but also varies within a woman over time.

Population Average Models

## **Population Average Models**

- An alternative to random / mixed-effects models that is more robust to assumptions of:
  - distribution of random effects
  - correlation structure
- Estimates correlation structure from the data rather than assuming normality
  - Requires more clusters than observations per cluster
- Estimates regression coefficients and robust standard errors
  - commonly by Generalized Estimating Equations (GEE)

Levi Waldron

Population Average Models

## **Population Average Models**

• Compare mixed model multiple linear regression:

$$E[Y_{ij}|X_{ij}] = \beta_0 + \alpha_{0j} + \beta_1 X_{ij}, \alpha_{0j} \sim N(0, \sigma)$$

for subject i in group j.

• to a population average model:

$$E[Y_{ij}|X_{ij}] = \beta_0^* + \beta_1^* X_{ij}$$

- Interpretations of  $\beta^*$  and  $\beta$  are equivalent
- Numerically equivalent for linear and log-linear models (if specification of mixed model is correct), but not for logistic link.

## Correlation assumptions for GEE

Must make some assumption about the form of correlation among grouped observations. Some options are:

- Independence:
  - no correlation between measurements within group
- Exchangeable:
  - all pairwise correlations are the same (in large-N limit)
  - nothing distinguishes one member of a cluster from another
  - appropriate in the absence of other data structures such as measurements taken through time or space
- Auto-regressive (AR-M):
  - observations taken more closely in time are more highly correlated

## Correlation assumptions for GEE (cont'd)

- Unstructured:
  - estimates a separate correlation between observations taken on each pair of "times"
- Non-stationary ("non\_stat\_M\_dep"):
  - similar to unstructured, but assumes all correlations for pairs separated far enough in time are zero
- Stationary ("stat\_M\_dep"):
  - e.g. stationary of order 2: observations taken at time points
     1 and 3 have the same correlation as time points 2 and 4
  - but this might be different from the correlation between observations taken at times 2 and 3
  - correlations for observations 3 or more time periods apart assumed to be zero

Fewer assumptions requires more data, and good assumptions improve results

## Help in choosing a method

Characteristic	Marginal	Fixed-effect	Mixed-effect
Distinguishes observations belonging to the same or different subjects	Yes <sup>a</sup>	Yes	Yes
Reliant on distribution of subject-specific effects	No	No	Yes
Subjects considered a sample from a population larger than the sample itself	Yes <sup>a</sup>	No	Yes
Computation handles few subjects well	No	Yes	No
Computation handles a very large number of subjects well	Yes	No	Yes
Noisy for few observations per subject	No	Yes	No
Computation handles a large number of observations per subject	Depends <sup>b</sup>	Yes	Yes
Accommodates variable observations per subject	Yes	Yes	Yes

Note: aOnly for calculation of standard errors.

<sup>b</sup>Problems can arise under some specifications of the working covariance structure and depending on the estimation method used.

### **Conclusions**

- Ignoring within-subject correlations can produce very wrong results, and is not always "conservative"
- Hierarchical analysis strategies are needed for any of:
  - 1 When the correlation structure is of primary interest, e.g. familial aggregation of disease, or consistency of treatment within centers,
  - 2 When we wish to "borrow strength" across the levels of a hierarchy in order to improve estimates, and
  - 3 When dealing with unbalanced correlated data. E.g., no requirement that each Georgia mother have exactly 5 children.
- Population average models provide a robust alternative to mixed models
  - for one level of hierarchy

## A final note on reporting results of hypothesis tests

- Include test statistic, a measure of "effect size", and test name if unclear from test statistic
- Write in plain language and let the statistics support, not lead. E.g.:
  - do: The 36 study participants had a mean age of 27.4 (SD = 12.6), significantly older than the university mean of 21.2 years (t(35) = 2.95, p = 0.01).
  - don't: A p-value of 0.01 indicated significant difference in age of study participants compared to all university students.
  - do: report confidence intervals where possible
- UW "Reporting Results of Common Statistical Tests in APA Format": specific examples of reporting a hypothesis test result
- STROBE guidelines for reporting observational studies: https://www.strobe-statement.org/
- A Guideline for Reporting Results of Statistical Analysis in Japanese Journal of Clinical Oncology: helpful guidelines for all parts of a manuscript
